

EXP NO:1	Comparative Study of Low-Code Development
-----------------	--

Aim

To analyze and compare Low-Code Development and Traditional Application Development approaches based on factors such as development speed, coding effort, flexibility, cost, and usability.

Theory

Low-Code Development is designed to simplify the process of building applications by providing ready-made components, visual interfaces, and automated functionalities. It reduces the need for extensive coding and allows faster development, making it suitable for quick solutions and business applications.

Traditional Application Development follows a detailed coding approach where developers write programs using languages and frameworks. It provides complete control over the application and allows the development of highly customized and complex systems, but it requires more time, effort, and expertise.

Comparison Table

Aspect	Low-Code Development	Traditional Application Development
Development Approach	Visual-based design with ready-made components	Code-centric development using programming languages
Coding Effort	Minimal coding required	Extensive coding required
Skill Requirement	Suitable for beginners and non-developers	Requires skilled programmers and technical expertise
UI Development	Built using drag-and-drop tools and templates	Designed manually using frontend technologies
Development Time	Faster application development	Time-consuming development process

Flexibility	Limited by platform capabilities	Highly flexible with full control over features
Cost	Lower cost due to reduced development time	Higher cost due to longer development and skilled resources
Maintenance	Easier with built-in tools	Requires continuous manual updates and debugging

Result

Thus, Low-Code Development enables faster and easier application development with less coding effort, while Traditional Development offers greater flexibility and control. The choice depends on the application requirements, complexity, time, and cost constraints.
